Lab-06 Report: Generated 2026-11-09 20:15

Names:

Group Name:

- **Q1.1):** Complete the implementation of `build_vocab()` below. The variable `unique_chars` is provided as a sorted list containing every unique character in the corpus. Use the `enumerate()` function to efficiently iterate through this list and construct both lookup dictionaries. Below, briefly describe your implementation.
- **A1.1):** We first describe our dictionarys as empty, then we enumerate all the unique chars and construct the two mirrored dicts by appending via the update funtion.

```
def build_vocab(text):
    """Builds character-to-index and index-to-character mapping
dictionaries."""
    unique_chars = sorted(list(set(text)))

# YOUR CODE STARTS HERE
    char_to_idx = dict()
    idx_to_char = dict()
    for i, c in enumerate(unique_chars):
        char_to_idx.update({c: i})
        idx_to_char.update({i: c})

# YOUR CODE ENDS HERE

    return char_to_idx, idx_to_char

# Call the function
char_to_idx, idx_to_char = build_vocab(cleaned_text)

# Print out the mappings to verify
print(char_to_idx)
print(idx_to_char)

for char in "cat":
    print(char_to_idx[char])
```

- **Q1.2:** One of the preprocessing steps performed by our text-cleaning function is converting all letters to lowercase. Suppose instead that we preserved capitalization, treating `"A"` and `"a"` as distinct tokens. How would this affect the vocabulary size and the token-to-index mappings generated by `build_vocab()`? Discuss both the potential advantages and disadvantages of retaining capitalization when training a language model.
- **A1.2:** It would double the number of distinct tokens (roughly) as every character would recieve a capital equivalent. The benefit is it allows the model to produce ALL CAPITAL TEXT TO SIMULATE YELLING as well as recognize if the user is yelling at them! In all seriousness it would just give the model more context to tone, ability to format sentences more clearly, at the cost of more parameters and compute and training needed.

- **Q1.3):** Our cleaning function `clean_text()` removes **all** numeric digits from the corpus. What effect would this have on a Wikipedia-trained model's ability to generate or reason about dates, quantities, or years? Would this be a bigger or smaller problem for a character-level model vs. a word-level model?
- **A1.3):** It would be a bigger problem for character level as it might not be able to understand or get dates at all. Word level models at least are able to encode english versions of numeric digits (like, one, two ... twenty seven thousand).

- **Q1.4:** Complete the implementation of `create_windows()` below by filling in the `for` loop. For each position `i`, generate an `input_seq` of length `seq_len` and a corresponding `target_seq` of the same length, where each character in the target sequence represents the expected next prediction for the corresponding input character. In space for your response below, briefly explain your implementation and describe how the generated input and target sequences are related.

- **A1.4:** Basically, we take a window of i to i+seq_len for the input, and then we offset by +1 for the targets so that we have the next character to predict.

```
def create_windows(numerical_text, seq_len):
    inputs = []
    targets = []
    for i in range(len(numerical_text) - seq_len):

# YOUR CODE STARTS HERE
        inputs.append(numerical_text[i:i+seq_len])
        targets.append(numerical_text[i+1:i+seq_len+1])
# YOUR CODE ENDS HERE

    return np.array(inputs), np.array(targets)
```

- **Q1.5:** Our current implementation produces a *many-to-many* training dataset, where each character in the input sequence has a corresponding target character prediction. How would the data-generation process need to change if we instead wanted to train a *many-to-one* model, where the goal is to predict just a single output and not a sequence? Describe the modification that would be required to `create_windows()`, and explain what the resulting input and target sequences would represent. You may either provide the modified code or describe the changes in words.

- **A1.5:** If we wanted to traim a many to one, your input would still be the same, but the output would just be i + seq_len + 1 to predict the next character AFTER the entire input sequence.

```
class WikipediaDataset(d2l.DataModule):
    def __init__(self, numerical_text, seq_len=12, batch_size=64):
        super().__init__()
        self.save_hyperparameters()

        # Split continuous numerical sequence to prevent train/val window
overlap
        total_len = len(numerical_text)
        split_idx = int(total_len * 0.8)

        # Create X_train/Y_train and X_val/Y_val windows, and store them as
tensors

# YOUR CODE STARTS HERE
        self.X_train, self.y_train =
create_windows(numerical_text[:split_idx], seq_len)
        self.X_train = torch.tensor(self.X_train)
        self.y_train = torch.tensor(self.y_train)
```

```
        self.X_val, self.y_val =
create_windows(numerical_text[split_idx+1:total_len], seq_len)
        self.X_val = torch.tensor(self.X_val)
        self.y_val = torch.tensor(self.y_val)
# YOUR CODE ENDS HERE

    def get_dataloader(self, train):
        if train:
            return self.get_tensorloader((self.X_train, self.y_train),
train=True)
        else:
            return self.get_tensorloader((self.X_val, self.y_val),
train=False)
```

- **Q2.1:** Complete the implementation of the `forward()` method below. Begin by using `torch.nn.functional.one_hot()` to convert each token index in `X` into a one-hot encoded representation, expanding every integer token ID into a sparse vector containing a single 1 and zeros elsewhere. Once the data has been encoded, pass it through the embedding, LSTM, and output layers defined in the `__init__()` method to produce the model's predictions. In the space for your response below, briefly explain your implementation. If you encountered any difficulties while completing this section, describe the source of the confusion and how you resolved it. In particular, consider whether the challenge involved one-hot encoding, tensor shapes, embeddings, the LSTM layer, or understanding how the data flows through the network.
- **A2.1:** I was able to more or less copy the forward pass from lab 5. But then it turns out that I forgot to pass it through embedding!! After fixing that it was relatively straightforward.

```
@d2l.add_to_class(RNNLanguageModel_v1)
def forward(self, X):
        vocab_size = self.hparams['vocab_size']

# YOUR CODE STARTS HERE
        hot = torch.nn.functional.one_hot(X, vocab_size).float()
        embeds = self.input_projection(hot)
        output, (H, C) = self.lstm(embeds)
        logits = self.output(output)
# YOUR CODE ENDS HERE

        return logits
```

- **Q2.2:** Throughout previous labs, we have often used one-hot encodings for our target labels `y`, but this is the first time we have applied one-hot encoding to the input features `X`. Recall that when preparing the Wikipedia corpus, we

mapped every character in the text to a unique integer ID. Why can't we simply feed these integer IDs directly into the LSTM? What incorrect assumptions might the model make if it interpreted the token IDs as ordinary numerical values? Explain how the one-hot encoding performed inside `forward()` addresses this problem and allows the model to treat each character as a distinct token rather than a quantity.

- **A2.2:** It could potentially not interpret it as actual token encodings and rather just try and predict numerical values. THe one hot encoding will prevent it from predicting non-token integers and keep it strictly predicting tokens and not some other numerical values.

- **Q2.3:** A language model achieves a cross-entropy loss of 0.00 on a dataset. Compute the corresponding perplexity and explain what this reveals about the model's predictions. Is such a result likely to be observed in practice? Why or why not?

- **A2.3:** The perplexity would then be 1.0. It would be easy to say 0 but because its e^Loss e^0 is 1. This reveals how the model gets more and more confident and has better predictions it gets closer to 1.0. It is unlikely for this to actually occur, as the model will almost never give a particular token 100% confidence.

- **Q2.4:** How does an autoregressive language model generate text from an initial prompt? Complete the `for` loop inside `predict_text()` to implement *greedy sampling* and then explain how the model's predictions are used to construct longer sequences of text. At each iteration, perform another forward pass through the model, extract the logits corresponding to the final time step, and select the token with the highest predicted probability using `argmax()`. This approach is known as *greedy* sampling because, at each step, we simply choose the most likely next token according to the model. Once selected, append the predicted token to the current sequence and continue generating text.

- **A2.4:** It generates text by prediciting one token (or character in this case) and then appends that to the input and feeds it back into itself.

```
def predict_text_v1(prefix, num_preds, model, char_to_idx, idx_to_char,
seq_len=12):
    #model.eval()

    # If the prefix contains characters not in the vocabulary, we can use a
special <unk> token or default to 0
```

```
    unk_id = char_to_idx.get('<unk>', char_to_idx.get('<UNK>', 0))
    outputs = [char_to_idx.get(ch, unk_id) for ch in prefix]

    with torch.no_grad():
        for _ in range(num_preds):

            # Grab the last seq_len characters to form the input sequence
            # Convert to tensors and feed into the model to get the next
character prediction
            # Take the argmax of the logits to get the predicted character
index
            # Add that index to the outputs list for the next iteration

# YOUR CODE STARTS HERE
            input_seq = torch.tensor(outputs[-seq_len:])
            pred_idx = (model(input_seq)[-1,:]).argmax().item()
# YOUR CODE ENDS HERE

            outputs.append(pred_idx)

    return "".join([idx_to_char.get(i, '<unk>') for i in outputs])
```

- **Q2.5:** How well does your model perform on previously unseen character sequences? Based on the output of `predict_text()` for several different prompts, what limitations do you observe in the generated text? In particular, discuss how the greedy sampling strategy, which always chooses the most probable next token, might affect the diversity, creativity, and long-term coherence of the model's predictions, especially when using a relatively simple character-level RNN.

- **A2.5:** So, it does follow at least some structure, it generated "and" twice but didnt generate proper words otherwise. Its clearly biased towards common letters and phrases which you can see there are a lot of 'a' characters so its not good for creativity...

- **Q3.1:** Complete the implementation of `build_word_vocab()` below. The variable counts contains the frequency of each word in the dataset. Use this information to create `top_words`, a list containing the `max_vocab_size - 1` most frequent words. Then prepend the special token `unk_token` to the beginning of this list (it is common practice to place special-purpose tokens at the start of a vocabulary) and use the resulting vocabulary to build both the `word_to_idx` and `idx_to_word` lookup dictionaries. In the response cell below, briefly explain your implementation. In particular, describe why we restrict the vocabulary size, the purpose of the `<UNK>` token, and how the lookup dictionaries enable conversion between words and numerical indices.

- **A3.1:** We cant allow a runaway vocabl list, as there are many tokens that would just show up one time and would otherwise be a wasted parameter. This is why we select k-1 top_words and add the unk token. The reason we add the unk token is because in a case where an input has a token that we excluded from out vocab. This unknown token is added to the vocab. Then we build the mirrored dictionaries (not sure if mirrored is the best term here) to encode/decode the tokens.

```
from collections import Counter

def build_word_vocab(tokens, max_vocab_size=10000, unk_token='<unk>'):
    # Frequency of each word
    counts = Counter(tokens)

    # Keep top (max_vocab_size - 1) most frequent words and include unk_token

# YOUR CODE STARTS HERE
    top_words = [word for word, count in counts.most_common(max_vocab_size -
1)]
    # Prepend unk_token to the beginning
    vocab = [unk_token] + top_words
    # build dicts
    word_to_idx = {word: idx for idx, word in enumerate(vocab)}
    idx_to_word = {idx: word for idx, word in enumerate(vocab)}

# YOUR CODE ENDS HERE

    return word_to_idx, idx_to_word

# Quick test of new function
tokens = tokenize_words(cleaned_text)
word_to_idx, idx_to_word = build_word_vocab(tokens, max_vocab_size=10)
print(word_to_idx)
```

```
{'<unk>': 0, '.': 1, ',': 2, 'the': 3, 'of': 4, 'to': 5, 'and': 6,
'wikipedia': 7, 'in': 8, 'a': 9}
```

- **Q3.2:** Compare the character-level vocabulary from the previous section to the word-level vocabulary used here. How does the change in vocabulary size affect the dimensions of our one-hot encodings? Why does this make `nn.Embedding` a more attractive choice than the one-hot encoding approach we used previously?

- **A3.2:** This increases the vocabulary, as before we only had each possible character with arrangement not mattering, but with words we have n^m possible vocabulary (where n is the amount of characters) for m size words (but the size for words is also variable!). nn.Embedding is more attractive as it is

much more efficient for larger sets than one-hot encodings as it is a learnable lookup table.

- **Q3.3:** Complete the updated `predict_text()` function by filling in the `for` loop. At each iteration, perform a forward pass through the model, extract the logits corresponding to the final time step, and use `argmax()` to select the model's prediction through greedy sampling. In the response cell below, briefly explain your implementation. In particular, describe how the predicted word is incorporated back into the sequence and how this allows the model to generate text autoregressively, one word at a time.
- **A3.3:** Its basically the same as the charcter based prediction model but it predicts entire words from the vocab. It first gets and input sequence, converts it to a tensor, is fed into the model, the last prediction slice is grabbed, we take the most likely (argmax) and then append it to outputs. This is then passed back in autoregressively. The other difference is the indcies we are grabbing being 0, -1.

```
def predict_text_v2(prefix, num_preds, model, word_to_idx, idx_to_word,
seq_len=12):

    # Tokenize prefix string or accept pre-split list of words
    if isinstance(prefix, str):
        # Using simple space-split matching your tokenization
        tokens = prefix.lower().split()
    else:
        tokens = prefix

    unk_id = word_to_idx.get('<unk>', 0)
    outputs = [word_to_idx.get(w, unk_id) for w in tokens]

    with torch.no_grad():
        for _ in range(num_preds):

            input_seq = outputs[-seq_len:]
            tensor_seq = torch.tensor([input_seq], dtype=torch.long)
# YOUR CODE STARTS HERE
            pred_idx = model(tensor_seq)[0,-1].argmax().item()
# YOUR CODE ENDS HERE

            outputs.append(pred_idx)

    # Join decoded word tokens with spaces
    return " ".join([idx_to_word[idx] for idx in outputs])
```

- **Q3.4:** Each row of the embedding matrix (displayed above) represents a learned numerical representation of a word. Suppose we compute the cosine similarity between the embedding vectors for `"in"` and `"on"`, and then separately between `"in"` and `"wikipedia"`. Which pair would you expect to have the higher cosine similarity, and why? In your response, discuss how the meaning, usage, and context of words influence the embeddings learned by the model.
- **A3.4:** in and on would likely have a higher cosine similarity as both vectors would similarly imply position (in or on something) and while being different are used in similar contexts. Wikipedia being a special noun would likely not have much similarity as to in vs on.

- **Q4.1:** Briefly explain your implementation and discuss the role of each special token in the translation pipeline. Why can't we simply use the words themselves without introducing these additional tokens?
- **A4.1:** These tokens are important so the model knows when a sentence starts as ends, as well as the model being able to freely translate a sentence and decide when the sentence ends and being able to padd after the EOS. Without these tokens if we had max predictions longer than the actual translation the model would be forces to predict additional words, which would be an extention of the translation.

```
def build_vocab(sentences):
    """Builds a simple token-to-index map and index-to-token map from text
strings."""

    # Initialize with our standard mandatory special tokens
    word_to_idx = {"<PAD>": 0, "<UNK>": 1, "<BOS>": 2, "<EOS>": 3}
    idx_to_word = {0: "<PAD>", 1: "<UNK>", 2: "<BOS>", 3: "<EOS>"}

# YOUR CODE STARTS HERE
    index = 4
    for sentence in sentences:
        for word in sentence.split():
            #print(f"sentence: {sentence}, word: {word}, index: {index}")
            if word_to_idx.get(word) is None:
                word_to_idx.update({word: index})
                idx_to_word.update({index: word})
                index += 1

# YOUR CODE ENDS HERE
    return word_to_idx, idx_to_word
word_to_idx_src, idx_to_word_src = build_vocab(english_sentences)
```

```
word_to_idx_tgt, idx_to_word_tgt = build_vocab(french_sentences)
print(word_to_idx_src)
```

- **Q4.2:** Notice that we construct `src_tokens` and `tgt_tokens` slightly differently:

  - `src_tokens` includes an `<EOS>` token, but no `<BOS>` token
  - `tgt_tokens` includes both a `<BOS>` token and an `<EOS>` token

  Why does the target sequence require a `<BOS>` while the source sequence does not? In your response, consider how the decoder generates translations and explain how the `<BOS>` token provides a starting point for the translation process.

- **A4.2:** The target needs to specify the begining of sentence, as we will be training the model to start with the target and then in the prediction label it will start with a BOS as it decodes. This marks the start of the translated sentence through the decoder.

- **Q4.3:** Complete the `__init__()` method below by utilizing the helper functions defined throughout this section to build the vocabularies, construct the lookup dictionaries, numericalize the sentence pairs, and create the tensor representations used for training. In addition, record the size of both the source-language and target-language vocabularies by storing them as class attributes using `self.`.

When creating your `X` and `y` tensors, it will be important that you first shuffle them; note that there are many ways to do this, just ensure that your `X` and `y` remain aligned after. For bilingual datasets such as this one, why may it be particularly important that we randomly shuffle our data before assigning our training and validation subsets?

- **A4.3:** It would be important to shuffle the data before applying the split as we might otherwise accidentally introduce bias based on how the dataset is constructed, this ensures that the mixtures of sentences is randomized and likely more diverse/well spread between the training and validation set.

```
class EnglishFrenchDataset(d2l.DataModule):
    def __init__(self, raw_text, batch_size=128, max_seq_len=10,
max_sentence_words=8, train_val_split=0.8):
        super().__init__()
        self.save_hyperparameters()
# YOUR CODE STARTS HERE
        # Preprocess raw text into source (English) and target (French)
sentence pairs
        src_sentences, tgt_sentences = preprocess_text(raw_text,
max_words=max_sentence_words)
        # Build vocabularies and lookup dictionaries for both languages
        self.src_word_to_idx, self.src_idx_to_word =
build_vocab(src_sentences)
        self.tgt_word_to_idx, self.tgt_idx_to_word =
build_vocab(tgt_sentences)
        # Record vocabulary sizes as class attributes
        self.src_vocab_size = len(self.src_word_to_idx)
        self.tgt_vocab_size = len(self.tgt_word_to_idx)
        # Numericalize and build fixed-length tensor representations
        self.src_tensors, self.tgt_tensors = build_tensor_arrays(
            src_sentences, tgt_sentences,
            self.src_word_to_idx, self.tgt_word_to_idx,
            max_seq_len=max_seq_len
        )
# YOUR CODE ENDS HERE

        # Create shuffled indices for tensors, keeping X and y aligned
        indices = np.random.permutation(len(self.src_tensors))

        self.X = self.src_tensors[indices]
        self.y = self.tgt_tensors[indices]
        self.num_train = int(len(self.X) * train_val_split)

    def get_dataloader(self, train=True):
        i = slice(0, self.num_train) if train else slice(self.num_train, None)
        return self.get_tensorloader((self.X, self.y), train, i)
```

- **Q5.1:** Complete the `forward()` implementation below by first applying the embedding layer to `X` and then passing the embedded sequence through the GRU. The GRU will return outputs, containing the hidden states for every time step in the sequence, and `h_n`, the final hidden state. In this architecture, `h_n` serves as the context vector that will be passed to the decoder.

  Briefly explain your implementation and identify the shapes of the major tensors involved. What is the shape of `X` before and after the embedding layer? What are the shapes of `outputs` and context_vector (`h_n`), and what does each tensor represent?

- **A5.1:** X after the embedding goes from size (batch, seq_len) to (batch, seq, embed_size). The output size is (batch_size, sseq_len, num_hidden) and the final context vector is (num_layers, batch_size, num_hidden)

```
@d2l.add_to_class(Encoder_v1)
def forward(self, X):
# YOUR CODE STARTS HERE
    embed = self.embedding(X)
    outputs, h_n = self.rnn(embed)
    context_vector = h_n
# YOUR CODE ENDS HERE
    return context_vector
```

- **Q5.2:** Complete the decoder's `forward()` method below by applying the embedding layer, passing the resulting sequence through the GRU, and projecting the GRU outputs into the target-language vocabulary using the final linear layer. The function should return both the output logits and the updated hidden state produced by the GRU.

  The context vector generated by the encoder serves as the decoder's initial hidden state, `h0`. In your response below, briefly explain your implementation and answer the following questions:

  - What is the shape of context_vector (`h0`)?
  - What information does `h0` contain when the decoder begins generating a translation?
  - Why is the context vector often described as an *information bottleneck*?
  - What information about the original input sequence may be lost when an entire sentence is compressed into a single fixed-size vector?
- **A5.2:** The context vector is the same shape as the output of the encoder, being (num_layers, batch size, num_hidden). When being put in, it provides the

compiled context inside the source sequence collapsed into a vector. This is a bottleneck as the models doesn't actually know the input tokens, but does know a compressed arbitrary representation on it. While some major features might be kept, the single fixed-size vector can only encode so much information, resuting in the words themselves and likely some semantic meaning with it being lost with it.

```
@d2l.add_to_class(Decoder_v1)
def forward(self, Y, context_vector):
# YOUR CODE STARTS HERE
    embed = self.embedding(Y)
    outputs, state = self.gru(embed, context_vector)
    logits = self.linear(outputs)
# YOUR CODE ENDS HERE
    return logits, state
```

- **Q5.3:** In step 3, we extract `logits` using `logits[0, -1, :]`. What do the indices 0 and -1 represent in this tensor?
- **A5.3:** its the first batch (0), at the last sequence (-1), and the target vocab.

- **Q5.4:** Why do we set `tgt_tensor = torch.tensor([[tgt_tokens[-1]]])` inside the loop instead of passing all previously generated tokens? In other words, what would be different if we instead set `tgt_tensor = torch.tensor([tgt_tokens])`?
- **A5.4:** The hidden state already keeps track of the entire input sequence, but doesn't update. Passing the whole sequence could potentially allow the RNN to read through what it is writing on each update at the cost of increasing the compute complexity from constant to n. The context vector doesn't appear to update after the initial encoding.

- **Q5.5:** Evaluate the performance of your translation model using several of the example sentences above (and any additional test sentences you would like to try). What aspects of the translations appear to be working well, and where does the model struggle? Consider factors such as vocabulary usage, grammar, word order, sentence length, and overall translation quality. Based on the outputs you observe, what do you think are the primary limitations of this encoder-decoder architecture?

- **A5.5:** The french looks much more reasonable and human readable than the earlier wikipedia model. Like, hello was properly translated to bonjour, I see ne comprends which likely means I dont understand. However, The last example "I am going to the school to play basketball" the model incorrectly guesses "cinema" and ends too early which is wrong.

- **Q6.1:** In the Bahdanau attention mechanism presented above, the queries originate from the decoder, while the keys and values originate from the encoder. This arrangement allows the decoder to determine which parts of the input sequence are most relevant when generating its next token.

  Suppose instead that we wanted to apply attention *within the encoder* itself, before the decoder ever runs. Where would the queries, keys, and values come from in that case? Describe what these vectors would represent and explain how the encoder could use them to determine which parts of the input sequence are most important.

- **A6.1:** Hmmm, what if attention is all we need.. We could apply attention to the input sequence as is with each input token attending to the previous input tokens to build the Key and Value matricies and learn these representations rather than only applying it during decode. These vectors would encode how related each token is to each other input token and could be used by the model to determine which words are the most important for the context...

- **Q6.2:** Before combining the query vector $\mathbf{q}$ and key vector $\mathbf{k}_i$, we first transform them using the learned weight matrices $\mathbf{W}_q$ and $\mathbf{W}_k$. Why are these linear transformations necessary? What advantages do they provide when comparing queries and keys?

  Suppose we instead tried to compute the alignment score using $\mathbf{q} + \mathbf{k}_i$ directly, without applying $\mathbf{W}_q$ and $\mathbf{W}_k$. What limitations or potential problems might arise? Consider both the dimensions of the vectors and the model's ability to learn meaningful relationships between different parts of the sequence.

- **A6.2:** If you couldn't apply a weighted transform then the model would be unable to learn the weights (relation) between each q and k. If it was fixed without a transform than every q would only apply to its own k but not have a relation to others. A little handwavy, but the weight matrixes are needed for the model to actually learn the relations between queries and keys.

- **Q6.3:** Finish the `__init__` block below. How does the shape of the reduction vector `V` differ from the other two linear projection layers defined here?
- **A6.3:** V projects the W * q + W * k in the tahn from hidden_size down to a singular scalar score rather than project it into hidden size.

```
class BahdanauAttention(nn.Module):
    def __init__(self, hidden_size):
        super().__init__()
# YOUR CODE STARTS HERE
        self.W_q = nn.Linear(hidden_size, hidden_size, bias=False) # intit
quiery weight matrix
        self.W_k = nn.Linear(hidden_size, hidden_size, bias=False) # init key
weight matrix
        self.V = nn.Linear(hidden_size, 1, bias=False) # initi Vector matrix
# YOUR CODE ENDS HERE
```

- **Q6.4:** Finish the `forward` implementation below. In accordance to the mathematical functions shown above, `attention_scores` should be calculated as the linear function `V` of the `tanh` applied to the broadcasting of the `queries` and `keys`. Then, the attention_weights can be calculated as the softmax of the scores using `F.softmax`.

  Document the shape of your current tensor after each step, from `scores` to `context_vector`. Why must we transpose `attention_weights` before performing the final matrix multiplication?
- **A6.4:** After the first step (calculating alignments), our shape is [N,T,1] which is from tanh(W_q + Wk) = [B,T,A] which then .V() -> to [N,T,1]. The attention weights take in the alignments and give out softmax over dim=1 so the shape is [B,T,1] (where B is batch, T is sequence length, A is attention hidden size)

```
@d2l.add_to_class(BahdanauAttention)
def forward(self, query, keys, values):
# YOUR CODE STARTS HERE
        alignments = (self.V(torch.tanh(self.W_q(query) + self.W_k(keys)))) #
compute alignment scores
        attention_weights = F.softmax(alignments, dim=1) # compute attention
weights
# YOUR CODE ENDS HERE

        # Multiply weights by Values to get the Context Vector
        # Shape: [Batch, 1, Hidden_Size]
        context_vector = torch.matmul(attention_weights.transpose(1, 2),
values)
```

```
        return context_vector, attention_weights
```

- **Q6.5:** Finish the implementation below by completing the `for` loop. Inside the loop, you are already provided the variable `current_word` and the `query`, derived from reshaping the hidden state `h`. You must calculate the `context` and `weights` by running the query through our attention layer. Then, you will want to use the `torch.cat` function to combine the embedding and the context vector before stepping the GRU forwards to calculate the `logits` and hidden state `h`. In your own words, describe how the feedback loop of the hidden state `h` allows the decoder to shift its attention dynamically to different tokens.

- **A6.5:** Each new hidden state is based on the sum of the previous ones but is preserved. This allows the model to shift its attention to any given previous hidden state, where this attention also influences the next hidden state.

```
@d2l.add_to_class(Decoder_v2)
def forward(self, X, state):
        encoder_outputs, h = state
        word_vectors = self.embedding(X) # [Batch, Seq_Len, Embedding_Dim]
        all_logits = []

        for t in range(X.size(1)):
                current_word = word_vectors[:, t:t+1, :]
# YOUR CODE STARTS HERE
                query = h.transpose(0,1) # reshape from 1, batch, hidden to
batch, 1, hidden
                context, weightes = self.attention(query, encoder_outputs,
encoder_outputs) # compute context vector )batch, src seq len, hidden)
                gru_input = torch.cat([current_word, context], dim=-1) # Add
current token (batch, 1, embedding_dim + hidden size)
                out, h = self.gru(gru_input,h) # get output from gru -> output
shape (batch, 1 ,hidden_size)
                logits = self.output(out) # Get logits -> shape (batch, 1,
vocab size)
                all_logits.append(logits) # append logits

# YOUR CODE ENDS HERE
        # Return predictions and the updated state [encoder_outputs, h]
        return torch.cat(all_logits, dim=1), [encoder_outputs, h]
```

- **Q6.6:** Did the introduction of attention into our architecture lead to improved translations? Compare and contrast to the prior encoder-decoder architecture. Use similar sentence prompts for your comparison.

- **A6.6:** Well, the three that were put out were not really better. The first one should be people lift weights at the gym but translated to the people argument the radio (roughly.). The third one is complete gibberish, compared to the previous model which got some actually correct. We put in the original senetences from before and it couldnt get any the previous one got like "I dont understand what youre saying".

- **Q7.1:** Transformers use sinusoidal positional encodings to provide information about the order of tokens in a sequence. Why might sine and cosine functions be more effective for this purpose than a simple positional numbering scheme such as $(1, 2, 3, 4, \dots)$? Consider how the model might infer both the absolute and relative positions of tokens. What are the potential advantages and disadvantages of using sinusoidal functions to represent sequence order.
- **A7.1:** A sinusoidal encoding could be better at letting a model learn relative positions as the wave function oscilating the model can learn that a token near the top of the wave is more related to tokens also near the top of the band, while simple positional encodings might be superior for absolute the model will only be able to learn relative encodings if the training data consistently covers the whole range (which it almost certainly wont).

- **Q7.2:** Examine the positional-encoding heatmap. Why does the left side of the figure (corresponding to lower embedding dimensions) appear as a rapidly alternating checkerboard pattern, while the right side (higher embedding dimensions) appears as broad, slowly varying stripes? What does this tell us about the types of positional information being encoded at different dimensions, and why is this useful for a Transformer?
- **A7.2:** This is useful, as closer to the left alternates faster which helps the model more accurately see the fine-grained distance for close tokens, but tokens far away (near the right) are generally just "far" away. This is helpful as generally data is going to be related to the data nearby, and the further the data the less and less relavent it gets until its so far away that one token to another far away doesn't carry much meaning to the current.

- **Q7.3:** In this formula, why do we divide by $\sqrt{d_k}$ (where d_k is the dimension of the keys)? Consider the role of the `softmax` when determining this.

- **A7.3:** It is to scale the values down before multiplying by V. This scaliing prevents the softmax function from being saturated (i.e. picking one class as 1 with others as 0) which is important for preventing vanishing gradients.

- **Q7.4:** Compare this formula to the Bahdanau Attention Mechanism formula we used before. In practice, scaled dot product attention is computationally much faster; looking at the formulas, why would that be?
- **A7.4:** This is because in Bdu attention you also have the RNN hidden state aspect, requring you to compute it by hidden as well. Removing the R part of the NN you simplify it by a large factor.

- **Q7.5:** Finish the `forward` implementation below. `scores` should be calculated as the Scaled Dot-Product as defined above using the `matmul` function for matrix multiplication; don't apply the softmax until you calculate `attention_weights`. Then, the context vector can be defined as the matrix multiplication of `attention_weights` and `V`. The reshaping of `context` is provided for you; what does it's shape look like after the final 2 lines? What was it's shape after the matrix multiplication before the permutation was applied?
- **A7.5:** See the shapes we have inserted into the comments of the code blocks :)

```
@d2l.add_to_class(MultiHeadAttention)
def forward(self, queries, keys, values, mask=None):
        # Shapes: [Batch, Seq_Len, num_hiddens]
        batch_size = queries.shape[0]

        # Project and split into heads
        Q = transpose_qkv(self.W_q(queries), num_heads=self.num_heads,
head_dim=self.head_dim)
        K = transpose_qkv(self.W_k(keys), num_heads=self.num_heads,
head_dim=self.head_dim)
        V = transpose_qkv(self.W_v(values), num_heads=self.num_heads,
head_dim=self.head_dim)
# YOUR CODE STARTS HERE

        scores = torch.matmul(Q, K.transpose(-2, -1)) / (self.head_dim ** 0.5)
# Attention scores from eq above!

        if mask is not None:
                # True means attention is allowed :p
                if mask.dim() == 3:  # [batch, query_len, key_len]
                        mask = mask[:, None, :, :]
                scores = scores.masked_fill(mask == 0, float("-inf")) #make
sure we dont mess up the softmax part!
```

```
# YOUR CODE ENDS HERE
        attention_weights = torch.softmax(scores, dim=-1) # [B, h, Lq, Lk] (Lq
= length of query, Lk = length of key, B = batch size, h = heads, d = head
dim, D = num hiddnes!)
        attention_weights = self.dropout(attention_weights) # B, h, Lq, Lk

        context = torch.matmul(attention_weights, V) # [B, h, Lq, d]
        context = context.permute(0, 2, 1, 3).contiguous() # [B,Lq,h,d]

        context = context.view(batch_size, -1, self.num_hiddens) # B, Lq, D
(merges the last two dims, h and d h(dot)d=D)
        return self.W_o(context) # [B, Lq, D]
```

- **Q7.6:** Finish the `forward` implementation below. First, our data `X` needs to be passed through our Multi-Head Attention layer, before applying the first residual connection and layer normalization. Then, run `X` through the Feed-Forward network, applying the second residual connection and layer normalization after to produce the final output. How does adding `X` back to the output in the residual connections stabilize our gradients? Additionally, can you tell why Layer Normalization works better than Batch Normalization for our task at hand?

- **A7.6:** Adding X back in will ensure that the residuals keep the baseline level form the normalized input + attention score. This prevents gradients from vanishing by ensuring this baseline value and the layer normalization prevents exploding gradients. Layer normalization likely would work better as is is more granular (per token) so it doesn't need the other valuies in the batch. The batch norm would also be hurt by varaible lengths and padding.

```
@d2l.add_to_class(Encoder_v3)
def forward(self, X, mask=None):
# YOUR CODE STARTS HERE
        attention_output = self.attention(X, X, X, mask)
        X = self.norm1(X + attention_output)

        ffn_output = self.ffn(X)
        X = self.norm2(X + ffn_output)
# YOUR CODE ENDS HERE
        return X
```

- **Q7.7:** Finish the `forward` implementation below, handling self-attention, cross-attention, and the feed-forward network. The data `X` should also be layer-normalized after each of these passes.

- **A7.7:**

```
@d2l.add_to_class(Decoder_v3)
def forward(self, X, encoder_outputs, tgt_mask=None, src_mask=None):
# YOUR CODE STARTS HERE
        self_attn_output = self.self_attention(X, X, X, tgt_mask) # compute
self attention
        X = self.norm1(X + self_attn_output) # Get layer norm value

        cross_attn_output = self.cross_attention( # cross attetnion time with
the norm input, encoder outputs, and source mask!
        X, encoder_outputs, encoder_outputs, src_mask
        )
        X = self.norm2(X + cross_attn_output) # Layer norm the cross attn

        ffn_output = self.ffn(X) # finally, feed forward network!
        X = self.norm3(X + ffn_output) # residual with layer norm, again.
# YOUR CODE ENDS HERE
        return X
```

- **Q7.8:** Finish implementing `forward` below. To do this, you need to handle running the encoder and decoder pipelines, embedding the tokens, applying our positional encoding to them, and generating outputs from the core models. Then, you can extract `logits` from the final dense linear layer as the return value. This is also an important point to reflect on all that we have done here; this is a pretty complicated architecture we are attempting. Briefly describe how each line of code here fits into the bigger picture of the transformer pipeline.
- **A7.8:** man, I love abstractions

```
@d2l.add_to_class(TransformerSeq2Seq)
def forward(self, src_tokens, tgt_tokens, src_mask=None, tgt_mask=None):
# YOUR CODE STARTS HERE
        src_embeddings = self.src_embedding(src_tokens) # embed inputs
        src_positioned = self.encoder_pos(src_embeddings) # get positional
encoded embeddings
        encoder_outputs = self.encoder_layer(src_positioned, src_mask) # get
the encoder outputs for source

        tgt_embeddings = self.tgt_embedding(tgt_tokens) # get the target
embeddings
        tgt_positioned = self.decoder_pos(tgt_embeddings) # Get positional
embeddings for targets
        decoder_outputs = self.decoder_layer( # get decoder outputs via
feeding in both the target positional embeddings alongside the encoder output
and masks.
                tgt_positioned, encoder_outputs, tgt_mask, src_mask
        )

        logits = self.dense(decoder_outputs) # finally, get the logits from
```

```
the dense layer of the decoder output
# YOUR CODE ENDS HERE
        return logits
```

- **Q7.9:** Based on that description of `temperature`, what do you think are some text generation tasks that would benefit from a lower temperature, and what are some tasks that would benefit from higher temperature values?
- **A7.9:** Low temperature would be good for tasks that require very consistent sampling, like code generation where you would want correct syntax. Higher temerature would be good for narrative writing as it increases the variety and flow that the model could make which could make more interesting output.

- **Q7.10:** Look closely at the section of `translate_sentence` annotated step #2: Encode Once. `encoder_outputs` is computed outside of the `for _ in range(max_generated_len)`, while `decoder_outputs` is computed inside of the loop in step 3. Why are we only allowed to run the encoder once, while the decoder is run constantly for every single word?
- **A7.10:** The encoder takes the intial input sequence and encodes it once, the decoder is autoregressive so it runs for every single output word.

- **Q7.11:** In step 3, we extract `next_token_logits = logits[0, -1, :]`. Why do we slice at index `-1` i.e. what does this index physically represent? If the target vocabulary had 5,000 words, what would be the shape/size of `next_token_logits`?
- **A7.11:** The next logits would be the lastest slice of logits in the current sequence, so you compute the next batch of logits, then grab that last batch.

- **Q8.1:** Based on these descriptions, what different language tasks would each of these models perform best in, and which would each be weaker in?
- **A8.1:** I would guess encoder decoder transformers are best for translation tasks, as that is a sequence to sequence task. The ecoder only architecture would be good for filling in sections, as it needs both sequences from the left to right and right to left of the target. Decoder only would be best for more creative tasks or really expensive auto-complete.

- **Q8.2:** Find the `SelfAttention` module parameters above. If the total model dimension d_{model} is 768, and the model uses 12 attention heads, what is the dimension d_k of the Query, Key and Value tensors? How does Multi-Head attention allow the model to focus on different parts of a sentence simultaneously?

- **A8.2:** d_{Query} is 768, so is key and value tensors. The multi-head attention allows the model to learn several different QKV projection matricies, so different heads can learn different types of "features" -- kind of similar to how CNN kernels can learn different patterns on an image.

- **Q8.3:** Finish the code block to grab the model's top 3 logits in the mask position and print them out. Once you grab the logits at the index position of the masked logit, you can use the PyTorch function `torch.topk()` where the parameters are `(masked_logits, k, dim)`. Then, write a simple label and `for` loop to print out the top 3 guesses.

  What approach did you have to use to collect the top 3 tokens into a usable data structure?

- **A8.3:** I got the mask indecies to get the mask logits. Using these logits I can get the top 3 ids using topk, which these ids can be converted back into the top 3 tokens!

```
with torch.no_grad():
    outputs = model_enc(**inputs)
    logits = outputs.logits

# Get top 3 predicted tokens for the <mask> slot
# YOUR CODE STARTS HERE
mask_index = (inputs["input_ids"][0] ==
tokenizer_enc.mask_token_id).nonzero(as_tuple=True)[0] # get mask index
mask_logits = logits[0, mask_index, :] # grab logits at the <mask> token
top_3_ids = torch.topk(mask_logits, k=3, dim=-1).indices # grab the top 3 ids
top_3_tokens = tokenizer_enc.convert_ids_to_tokens(top_3_ids[0].tolist()) #
using the ids, get the tokens!
for i in top_3_tokens:
    print(f"token {i}")
# YOUR CODE ENDS HERE
```

```
token Ġlive
token Ġgrow
token Ġcome
```

- **Q8.4:** While RoBERTa looked very similar to our architecture, GPT-2 has a few different components. Pay attention to the `Conv1d` layers in the model; we already know that convolutions are great for feature extraction and downsampling. Are these convolutions being directly used spatially/temporally across the sequences of data? What are the convolutions actually doing here? Hint: HuggingFace's GPT-2 implementation doesn't use a true spatial convolution here at all — it's a linear projection with the weight matrix stored transposed. Think about what that means for whether information can mix across different sequence positions.
- **A8.4:** These one dimensional convolutions are used as an attention mechanism, the first conv layer (c_attn) takes the input 2304 and outputs it to 768 dims. Then, the second one is a linear projection (c_proj) which takes it from 768 to 768 dims. This convolution allows each given token to attend to all others as it is 1 dimensional, if it was 2d then there would be inductive bias (receptive field) which would make the convolutional layers used spacially/temporally.

- **Q8.5:** Looking through the architecture for T5, you will not find any positional encoding or embedding layer. GPT-2 had `wpe` and BERT had `positional_embeddings`, but T5 never explicitly defined a positional injection. Then, how does T5 inform its attention heads about the spacial distance between tokens? Hint: The answer is called *relative position bias*, try to figure out the mechanism behind it on your own.
- **A8.5:** Relative attention bias injects positional infomration into the attention logits rather than the input token embedding. This allows the model to better grasp the concept of proximity by being able to generalize relationships across absolute positions rather than just putting the position into the input token embedding.

- **Q8.6:** Given everything you've seen from RoBERTa, GPT-2, and T5, if you needed to build a system that summarizes long documents into a few sentences, which architecture family would you start from, and why?
- **A8.6:** We would argue that T5 is likely the best summarizer as it is best for a sequence to sequence (the document is the input sequence, summary is the output). You could train this model on full-sequence pairs. GPT-2 is a likely option too, but only loses out because you dont want the summary to inform itself

which an autoregressive decoder like GPT-2 would to. BERT being encoder only is best for masking and would not be ideal for a sequence to sequence task.

Prelab Questions

- **Q0.1):** The space character is typically one of the most common tokens in an English text corpus. A student argues that spaces carry little useful information and should simply be removed before training the language model. Do you agree or disagree? Explain your reasoning and provide a specific example demonstrating how removing spaces could affect a model's ability to learn or generate language.
- **A0.1):** I think it depends on your use case. For just generating text like in BERT models you can strip the whitespace and you wouldn't see much of a change as generating exclusively english means you have many spaces. Other languages, particular Kanji based ones with varying spacing would almost certainly need to encode/decode spaces. However, for formatting, indentation, etc, having a model be able to understand and generate spaces and be worthwhile.

- **Q0.2):** Two language models are trained on the same dataset. Model A achieves a perplexity of 25, while Model B achieves a perplexity of 4. Which model would you trust more when generating text, and why? In your response, explain what perplexity measures and how it relates to a model's uncertainty when predicting the next token.
- **A0.2):** Probably model B unless I wanted to see some funny text as a lower perplexity means it has a higher confidence (kind of like an error rate). Effectively, higher confidence while being right -> Lower perplexity & more accurate text generation.

- **Q0.3):** An encoder-decoder model compresses an entire input sentence into a single fixed-size context vector before the decoder generates any output. Based on what you already know about information bottlenecks, predict one specific way this could cause problems when translating a long, complex sentence. You'll revisit this exact limitation in Section 6, but for now, just write down your prediction.
- **A0.3):** Likely some data loss, you can do a pretty close approximation but encoding it into a context vector would cause some inaccuracies. (the word compresses is hopefully a giveaway).
